What Is Page Object Model (POM)?

Definition: POM is a design pattern that models each web page as a class containing locators and actions, decoupling test logic from page structure.

Core Principle: Encapsulate element definitions and page operations within page classes; tests drive those methods without knowing locator details.

Benefits:

- **Maintainability** – Changing a locator in one place updates all tests.
- **Reusability** – Common page flows (login, navigation) live in page methods.
- **Readability** – High-level test scripts read like user stories.

Anatomy of POM

Page Class: Declares private locators (By or WebElement) and exposes public methods (e.g., login(username,password)), hiding implementation details.

Test Class: Instantiates page objects, calls methods to perform steps, and contains assertions verifying outcomes.

Base Test: Centralizes WebDriver setup and teardown, configures timeouts, and manages browser lifecycle.

Flow: Base Test → Page Object initialization → Test uses page methods → Assertions.
